6	Update	13
7	Quickstart	15
8	Hives	17
8.1	What is a Hive	17
8.2	Create a Hive	17
8.3	Add hive to HoneySwarm	17
9	Frames	21
9.1	What is a Frame	21
9.2	Create a Frame	21
10	Honeypots	23
10.1	What is a Honeypot	23
10.2	Existing Honeypots	23
10.3	Deploying Honeypots	23
10.4	Controlling Honeypots	24
10.5	Editing Honeypots	24
10.6	Creating New Honeypots	24
11	ElasticSearch	25

11.1	Installation	25
11.2	Migration	25
12	Indices and tables	27

CHAPTER 1

About

Honeyswarm is a Honeypot Orchestration and monitoring platform designed to make honeypots easy again

CHAPTER 2

Installation

The officially supported installation process is to use the docker-compose that is shipped with the repo. Installing in a method other than docker-compose is left as an exercise to the user. Read the compose and the docker files for each container should give you a headstart.

2.1 Docker and Compose

Install Docker and docker-compose using the official guides at <https://docs.docker.com/get-docker/>

2.2 HoneySwarm

If you want to run the latest stable release use the following docker-compose file and pin a release tag

```
version: '3.7'
services:
  honeyswarm:
    image: honeyswarm/honeyswarm
    container_name: honeyswarm
    env_file:
      - honeyswarm.env
    ports:
      - "8080:8080"
    networks:
      honeynet:
        ipv4_address: 10.1.0.101
    volumes:
      - "honeyswarmStates:/opt/honeystates/salt:rw"
    depends_on:
      - mongoserver
      - saltmaster
  mongoserver:
```

(continues on next page)

(continued from previous page)

```
image: mongo:latest
container_name: honeyswarm_db
env_file:
  - honeyswarm.env
ports:
  - '27017:27017'
networks:
  honeynet:
    ipv4_address: 10.1.0.102
volumes:
  - "honeyswarmDB:/data/db"
saltmaster:
image: "saltstack/salt:latest"
container_name: honeyswarm_saltstack
env_file:
  - honeyswarm.env
ports:
  - "8000:8000"
  - "4505:4505"
  - "4506:4506"
networks:
  honeynet:
    ipv4_address: 10.1.0.103
volumes:
  - "honeyswarmPKI:/etc/salt/pki:rw"
  - "honeyswarmStates:/srv/salt:rw"
hpfeeds-broker:
image: honeyswarm/honeyswarm_broker
container_name: honeyswarm_broker
ports:
  - "0.0.0.0:10000:10000"
networks:
  honeynet:
    ipv4_address: 10.1.0.104
env_file:
  - honeyswarm.env
depends_on:
  - mongoserver

networks:
honeynet:
  driver: bridge
  ipam:
    driver: default
    config:
      - subnet: 10.1.0.0/24

volumes:
honeyswarmDB:
honeyswarmPKI:
honeyswarmStates:
```

If you prefer a development version then `git clone git@github.com:honeyswarm/honeyswarm.git`

Create a `docker-compose.yml` file on the host you want to operate as the HoneySwarm Controller. Add the contents of the compose file from above.

Create a `honeyswarm.env` file in the same directory as the `docker-compose` and add the following content. The latest

version can be found in the git repo.

```
# Salt Master details
SALT_USERNAME=salt
SALT_SHARED_SECRET=supersecretsaltstackmasterstring
SALT_HOST=https://127.0.0.1:8000

# Flask Shell
FLASK_APP=honeyswarm.py
PYTHONPATH=/opt/
SESSION_SECRET=MuhktUNBDthagZkY477ZWcXfM41x5dRuao8eEXZK

# Mongo Details
MONGODB_HOST=127.0.0.1
MONGODB_PORT=27017
MONGODB_USERNAME=admin
MONGODB_PASSWORD=admin
MONGODB_AUTH_SOURCE=admin
MONGODB_DATABASE=honeyswarm
MONGO_INITDB_ROOT_USERNAME=admin
MONGO_INITDB_ROOT_PASSWORD=admin

# HPFeeds
WAIT_HOSTS=127.0.0.1:27017
```

2.3 Configuration

Copy `honeyswarm_template.env` to `honeyswarm.env` and change the default passwords and tokens as per the list below.

- `SALT_SHARED_SECRET`
- `MONGODB_USERNAME` and `MONGO_INITDB_ROOT_USERNAME`
- `MONGODB_PASSWORD` and `MONGO_INITDB_ROOT_PASSWORD`

Please leave all the HOST names and ports as they are pre configured.

If you wish to change the external HTTP port from 8080 to something of your choice edit the `docker-compose.yml` file.

Once you have made your changes you will need to start the application and complete the first time setup.

2.4 First Time Setup

Start HoneySwarm using the command `docker-compose up`. Refer to the Starting section for more details.

The first start will download all the required docker images and configure them as per the `.env` file.

Once you start your HoneySwarm instance for the first time you will need to run the initial installation. To start the install visit <http://HONEYSWARMIP:8080/install>

You should be presented with an installation form.

Welcome To HoneySwarm

Lets get a couple of things set up for you.

Currently Docker Compose is the only supported installation method. Please check all the base settings in the honeyswarm.env file before proceding.

Admin Email	Name
<input type="text" value="info@honeyswarm.org"/>	<input type="text" value="TheHermit"/>
Password	Confirm Password
<input type="password" value="....."/>	<input type="password" value="....."/>
Honeyswarm Host	Honeyswarm API
<input type="text" value="192.168.1.158"/>	<input type="text" value="4c481a335e42bca5266ff475e94af702"/>
Broker Host	Broker Secret
<input type="text" value="192.168.1.158"/>	<input type="password" value="....."/>

Fill all the required fields.

- Honeyswarm Host: This should be set to an IP address that your honeypot hosts (Hives) can access.
- Honeyswarm API: This will autofil with a randomly generated API Key, but you can change it. This is the key that will be used to run the initial Hive setup
- BrokerHost: This is the HPFeeds Broker IP, if your using the default installation this should be set to match the HoneySwarm Host fields
- Broker Secret: This is the main auth key that will be used to Subscribe to ALL incoming honeypot Events.

As part of the installation HoneySwarm will download and install all the available frames and honeypots.

Once the installation has completed you will need to stop and restart the docker-compose to restart all the services with the new configuration.

CHAPTER 3

Starting

All commands must be executed from the honeyswarm directory.

To start the application in the background enter `docker-compose up -d` in a terminal. To start the application in the foreground with visible logging enter `docker-compose up` in a terminal.

CHAPTER 4

Stopping

All commands must be executed from the honeyswarm directory.

```
docker-compose down
```

5.1 Volumes

To maintain persistence of data HoneySwarm uses docker volumes. As long as you do not prune or destroy these volumes you can start, stop and upgrade your HoneySwarm containers without losing data.

5.2 Backup

For details on backing up or restoring docker volumes please refer to the docker documentation.

CHAPTER 6

Update

If you're using docker-compose you can update your installation by following these steps.

Note This will take your hpfeeds broker offline for a few minutes and you will not store any incoming events.

- `cd` to the honeyswarm directory
- `docker-compose pull`
- `docker-compose up --force-recreate --build -d`

CHAPTER 7

Quickstart

8.1 What is a Hive

A Hive is a host device that is capable of running one or more honeypots. A hive can be a virtual machine a physical machine or an Amazon instance.

There are a few requirements that a hive must meet in order to deploy and run honeypots.

- Can connect to the internet.
- Can connect to the HoneySwarm controller
- Able to install and run docker containers
- Supports python >=3.7

8.2 Create a Hive

The first step is to initialise the Hive Host. We do this by installing a Salt Minion with some custom parameters. You can use the following examples to init a Linux or Windows Host replacing the IP address.

```
curl -H "Authorization: APITOKEN" http://HONEYSWARMIP:8080/hives/api/hive/register/linux | sudo sh
```

These command lines are also displayed in HoneySwarm on the hives page with your current API token.

This should install the base and register the hive with HoneySwarm. The next step is to approve the registration

8.3 Add hive to HoneySwarm

Once a Hive has been initialised we need to approve it in to the swarm. This prevents rogue hosts from connecting to us. You will only see the dropdown action once the Minion has started and sent its key to the master. Once available Just select the 'Add to swarm' button under actions

Registered Hives

Hive Name	OS	IP Address	Created	Last Seen	Frame	Honeypot Count	Actions
-----------	----	------------	---------	-----------	-------	----------------	---------

Unregistered Hives

Hive Name	Actions
pedantic_noyce	Add to Swarm Delete

Unresponsive Hives

Hive Name	OS	IP Address	Created	Last Seen	Frame	Honeypot Count	Actions
-----------	----	------------	---------	-----------	-------	----------------	---------

After the Hive is authenticated to the swarm you need to add a Frame. For more details on Frames see the Frames page.

All available frames will be displayed for Hives. To install a Frame click the Install button

Registered Hives

Hive Name	OS	IP Address	Created	Last Seen	Frame	Honeypot Count	Actions
pedantic_noyce	Ubuntu	192.168.212.129	26 Jul 2020 22:14	26 Jul 2020 22:20	Install Docker Linux Frame	0	Poll Restart Delete

Unregistered Hives

Hive Name	Actions
-----------	---------

Unresponsive Hives

Hive Name	OS	IP Address	Created	Last Seen	Frame	Honeypot Count	Actions
-----------	----	------------	---------	-----------	-------	----------------	---------

Frame installation can take several minutes depending on OS and internet speeds. You can track the installation under the /jobs page

With a frame installed we can now deploy some honeypots.

9.1 What is a Frame

ToDo

9.2 Create a Frame

ToDo

Now you have a frame install some honeypots :)

10.1 What is a Honeypot

ToDo

10.2 Existing Honeypots

- Apache
- Conpot
- Cowrie
- ElasticSearch
- SaltStack
- WordPress
- PortScans

10.3 Deploying Honeypots

To deploy a honeypot navigate to the honeypots page and from the Available Honeypots section Click *deploy* on the honeypot you wish to load.

From this pop up box you can configure any customisable options and then select the Hive you wish to deploy the honeypot to and Click the Deploy. In the background you should see a notification for a scheduled deployment. The Deployment pop up will stay active until you select close to enable multiple deployments.

Deploy Cowrie to an existing hive

Select Hive

Select...

Pillar Values

Pillar values can be used to customise certain aspects of your honeypot please refer to the Honeypot editor page for details on each of these options

Actions

Apache

10.4 Controlling Honeypots

You can Start, Stop and Delete individual Honeypots from teh Honeypots page.

Instance ID	Hive ID	Honeypot Type	Status	Actions			
5eb5d1461b270e45aa6fbbcf	5e5c1d9fe32f06de9d39ca24	SaltStack	running	<div>Poll</div>	<div>Start</div>	<div>Stop</div>	<div>Delete</div>
5eb5d1981b270e45aa6fbbd2	5e5c1d9fe32f06de9d39ca24	Cowrie	stopped	<div>Poll</div>	<div>Start</div>	<div>Stop</div>	<div>Delete</div>

10.5 Editing Honeypots

ToDo

10.6 Creating New Honeypots

ToDo

11.1 Installation

There is a customer docker-compose that you can use to additionally launch a single node ElasticSearch and Kibana stack. You will need to modify the default password to ensure that your Kibana instance is secured against unauthorised access.

11.2 Migration

If you already have data in your HoneySwarm you can add this data to your ElasticSearch using the following steps.

1. Connect to the HoneySwarm docker container
2. Start flask shell
3. Run the following python code.

```
import json
import datetime
from elasticsearch import Elasticsearch
elastic_client = Elasticsearch("honeyswarm_es01", http_auth=("elastic", "HoneySwarm"))
from honeyswarm.models import HoneypotEvents
events = HoneypotEvents.objects()
for event in events:
    # If you already have data in your elastic index use this datetime filter to avoid_
    ↳ duplicates.
    if event.date < datetime.datetime.strptime("2020-07-31 21:23:42.000000", '%Y-%m-%d %H:
    ↳ %M:%S.%f'):
        try:
            event_entry = json.loads(event.to_json())
            event_entry["event_id"] = str(event_entry['_id'])
            del event_entry['_id']
            event_entry['date'] = event.date
```

(continues on next page)

(continued from previous page)

```
instance_id = event_entry['honeypot_instance_id']
index_name = "honeyswarm-{0}".format(instance_id)
elastic_client.index(index=index_name,body=event_entry)
except Exception as err:
    print(err)
```

CHAPTER 12

Indices and tables

- `genindex`
- `modindex`
- `search`
